The object of this patent is to provide methods of aerospace propulsion in vertical and horizontal directions. In vertical propulsion, this invention circulates matter, within the confine of a machine, at speeds greater than the velocity required for circular orbit of the planet, so as to develop radial acceleration relative to the planet center, creating upward thrust. This method is referred to as "Gyroscopic Lift".

It is the further object of this invention to provide additional method of propulsion that may be applied in the horizontal direction. This invention alternates acceleration and deceleration of matter, as it travels in a circulatory system, so as to create a directional imbalance of forces on the geometric plane of circulation. Horizontal propulsion, for the device as a whole, is developed as a reaction to the change in velocity for particles within a closed system of circulation. This method is referred to as "Impulse Propulsion".
